Booking Software & Building Controlling System
Data Exchange Protocol
Nordic Standard

Draft 1
DocumentVersion 0.0.9
2016-10-14

Companies that conforms to this standard/document

Name	Country	Date	Contact	Color
Regler Och Webbteknik Sverige AB	Sweden	2016-09-21	Robin Andersson robin@rows.se	Yellow
Agrando Sweden AB	Sweden	2016-09-22	Rune Hansen rune.hansen@agrando.no	Blue
LJ System AB	Sweden	2016-09-23	Niklas Falemar niklas@ljsystem.se	Orange
Eniac Data AB	Sweden	2016-09-23	David Fröjmark david.frojmark@eniac.se	Green
JEFF Electronics AB	Sweden	2016-09-26	Björn Granbom bjorn@jeff.se	Red
Mild Media AB	Swden	2016-09-27	Albin Nystedt	Purple

Every change a company want to make to this document must be highlighted with corresponding color. When the change is unanimous and democratically decided to stay the color will be removed, and (very important) the fixed change must be noted/listed in the “Document version notes” section. Both of who asks and the one who approved the change must be noted.

Introduction

The goal with this standard is to simplify and unify the data exchanges between booking administration softwares and building controlling systems.

This standard is in its early stage and will be updated regularly in the coming year.

Abbreviations and explanations

Booking administration software: is referred to an administration software where a user has the ability to schedule the use of one or more resources.
In this document Booking Administration Software will be shorted to BAS.

Building controlling systems: is refereed to systems that in one way or another controls a building and/or its surroundings.
In this document Building Controlling Systems will be shorted to BCS.

Data Transfer

The data are to be transferred with HTTP or HTTPS as a POST method.

The URL shall always be the same regardless of what method is invoked.

All transfers are initiated by the BCS. Thus all requests will be made by a BCS and all responses comes from a BAS.

HTTP Keep-Alive are preferred.

Request/response payload

The payload data must be formatted as valid **JSON**.
All variable names are **case sensitive**.
The order of variables is **not predetermined** and can be in any order within the JSON object.
All ID values must be valid GUID/UUID string.
Every request must include a variable called “clientID” which contains a unique identification of the BCS system so that the BAS can filter unwelcome requests.
The JSON object must be passed as the body of the POST request.

TODO: A verification with some sort of hashing needs to be implemented.

Fetching customer data

This method requests information about the customer and their resources.

REQUEST

Name	Description	Note
method	Requested method. Every request must have this.	
version	Request version number as signed integer. This is to ensure that future changes that break backward compatibility does not destroy existing connections. The “version” value is divided into three parts. **Part 1:** API Level implementation. (see description) **Part 2:** Method version. Is only to be changed if backward compatibility is broken. **Part 3:** Documentation standard version. The BAS must return status.code = 460 or 461 if the version of part 1 or 2 is unknown. (See status.code section below) Part 3 should not create errors.	Changed the status codes from 1 and 2 to 460 and 461.
clientID	A unique identification of the BCS system. Must be GUID/UUID compatible. Every single BCSs should be able to have the same clientID between several BASs.	Changed the name from appId to clientID.
token	**Description to be filled in by Robin (ROWS)!**	
customers	A GUID/UUID list of requested customers. The customer id is determined in BAS and handed to BCS prior to installation.	

example:

```
{
        “method”: “GetCustomerData”,
        ”version”: “1.1.8”,
        “clientID”: “4e481c08-c808-4188-b128-20a5a02ebf96”,
        "customers": ["e3941203-37c8-4aaf-a10c-a46100ccb787"]

}
```

RESPONSE

Name	Description	Note
status	Must exist in all responses.	
status.code	Signed integer. Based on the HTTP standard codes (https://en.wikipedia.org/wiki/List_of_HTTP_status_codes). Future additions to the codes should if possible be based on it's HTTP counterpart or selected so that it doesn't conflict with any known HTTP code. **Success** **200** = OK *(All is good and data returned as requested.)* **201** = Created *(Data received and processed.)* **202** = Accepted *(Data received and are still being processed.)* **204** = No Content *(Request OK but no data returned.)* **299** = OK Deprecated *(Same as 200 except the method will be removed in next level. Alternative method might be suggested in status.msg.)* **Client Error** **400** = Bad Request *(Invalid JSON in request.)* **401** = Unauthorized *(Unknown clientID or invalid token.)* **405** = Method Not Allowed *(Requested method does not exist.)* **409** = Conflict *(Sent data already exist.)* **410** = Gone *(Method does not exist anymore. Must have returned 299 in previous level.)* **418** = I'm a teapot **460** = Level Version Out Of Range *(Requested level version not yet implemented.)* **461** = Method Version Out Of Range *(Requested method version not yet implemented.)* **Server Error** **500** = Internal Server Error *(Fatal error in BAS. Further debug error code may be added to status.msg.)* **OBS:** These codes, even though based on the HTTP response codes, should **not** be set in the response header as the HTTP code. The HTTP code should always be 200.	Added new status codes based on HTTP codes.
status.msg	Description of the warning or error. This should only be used by humans for debugging and not by the parser. If status.code 500 is returned, the message may include a code used by the BAS for	

	debugging.	
server	Object containing information about BAS server.	
server.supportedVersion	Highest supported version. The BCS should note this and conform to older version if BCS is more updated than the BAS.	
customers	A list of requested customers.	
customers.id	Customer id. The ID must be formated as a GUID/UUID. The generation of the ID is not specified.	
customers.name	The name of the customer within BAS.	
customers.resources	A list of resources this customer has created.	
customers.resources.id	A unique id for the resource. The ID must be formated as a GUID/UUID. The generation of the ID is not specified.	
customers.resources.name	The name of the resource in BAS. A rename of a resource in BAS should not alter the id. ***Optional:*** *if BCS wants to rename its resource/zone name automatically.* ***Optional:*** *if the BAS has hierarchic architecture and wants to display the full path. It should in that case be separated with a /*	

example:

```
{
        "status": {
                "code": 0,
                "msg": "ok"
        },
        “server”: {
                “supportedVersion”: “1.1.8”
        },
        "customers": [{
                "id": "e3941203-37c8-4aaf-a10c-a46100ccb787",
                "name": "Customer name",
                "resources": [{
                        "id": "5817c100-d599-4f2e-9c25-07e7a64075a0",
                        "name": "Location/resource one"
                }, {
                        "id": "fe77c299-980e-49a2-82a5-4f42a4cadf34",
                        "name": "Location/resource two"
                }]
        }]
}
```

Fetching resource data (string time and dates)

REQUEST

Name	Description	Note
method	See method: “GetCustomerData” for more info.	
version	See method: “GetCustomerData” for more info.	
clientID	See method: “GetCustomerData” for more info.	
token	**Description to be filled in by Robin (ROWS)!**	
dateFormat	Specifies what type of format the date and times must have in this request. Both the request and response must conform to selected format. “string” = Dates and times is to be represented as string in the format “yyyy-mm-dd hh:MM:ss” “epoch” = Dates and times is to be represented as Unix epoch times. The number of seconds that have elapsed since January 1, 1970 (midnight UTC/GMT) It must interpreted as UInt64	Removed that seconds is optional. We must know what to expect.
start	Specifies from what date and time (GMT time) the bookings should start. Every booking that has it’s start and/or end date **on or after** this time. If dateFormat is set to “epoch” this value must also conform to epoch standard and vise versa.	
end	Specifies from what date and time (GMT time) the bookings should end. Every booking that has it’s start and/or end date **before** this time. If dateFormat is set to “epoch” this value must also conform to epoch standard and vise versa.	
resources	A list of requested resources. The resources id is requested with method: “GetCustomerData” in beforehand.	

example:

```
{
        “method”: “ GetResourceData”,
        ”version”: “1.1.8”,
        “clientID”: “4e481c08-c808-4188-b128-20a5a02ebf96”,
        ”dateFormat”: ”string”
        "start": "2015-05-01",
        "end": "2016-05-01",
        "resources": [
                "5817c100-d599-4f2e-9c25-07e7a64075a0",
                "fe77c299-980e-49a2-82a5-4f42a4cadf34"
        ]
}
```

RESPONSE

Name	Description	Note
status	See method: “GetCustomerData” for more info.	
status.code	See method: “GetCustomerData” for more info.	
status.msg	See method: “GetCustomerData” for more info.	
list	The list of requested bookings. Booked start time < Requested end time and Booked end time > Requested start time	Formated.
list.id	Unique id for this specific booking instance. No duplicates! This is an “instance id”, not booking id. If the booking is a repeated booking “I.e every Sunday” every Sunday must produce its own unique id. This is to accommodate the future function to let the BCS report back information on past bookings to the BAS. The ID must be formated as a GUID/UUID. The generation of the ID is not specified.	
list.start	The start (GMT time) of the booking. Expressed as selected dateFormat.	
list.end	The end (GMT time) of the booking. Expressed as selected dateFormat.	
list.created	The date and time (GMT time) current booking was made in the BAS. Expressed as selected dateFormat.	
list.signature	A signature/name on the person who made the current booking.	
list.heat	Indicates what type of heat/temperature the booker wants on this particular booking. In the BAS this should be a dropdown or simular presented to the booker when the booking is made or the the template is defined. All values smaller than zero is predefined temperatures in BCS by the facility manager. -2 = Cleaning temperature. Predefined temperature for cleaning staff. -1 = No heat. The temperature should be the same as if there was no booking at this time. The humidity protection must also be active. This value is meant to be used when the resource is booked but no people will be there. 0 = Standard heat. No change. The predefined booked temperature is to be used. > 0 = Selected temperature. I.e value of 21 means	

	that the desired temperature for this booking is 21°C	
list.title	The title of this booking.	
list.resources	A list of resources that is booked in the same booking. This is for future functions. Like lightings and doors.	

example:

```
{
	"status": {
		"code": 0,
		"msg": "ok"
	},
	"list": [{
		"id": "afff431b-2835-45a1-9c5e-a100d746ea0c",
		"start": "2015-05-05 11:30:00",
		"end": "2015-05-05 12:00:00",
		”created”: ”2015-05-01 11:00:00”,
		”signature”: ”Eva Andersson”,
		"heat": 0,
		"title": "Booking with standard heat temp",
		"resources": [
			"fe77c299-980e-49a2-82a5-4f42a4cadf34"
		]
	}, {
		"id": "99c42508-0e9c-4eef-af19-d7dbb48f9b27",
		"start": "2015-04-30 18:30:00",
		"end": "2015-05-02 19:30:00",
		”created”: ”2015-04-01 11:00:00”,
		”signature”: ”Eva Andersson”,
		"heat": -1,
		"title": "Booking with no heat",
		"resources": [
			"5817c100-d599-4f2e-9c25-07e7a64075a0",
			"0f01ce5b-0c9b-4534-b1f1-f4891511ecb1"
		]
	}]
}
```

Document version notes

Notes 0.0.3:

1. ROWS
After a discussion between ROWS and Jeff a decision has been made to remove timezones. The goal is to always express dates and times in GMT (Greenwich Mean Time).
It will be up to the receiver of the data to convert the time to appropriate timezone and apply daylight savings if necessary. This is not democratically voted since the number of introduced companies is too low.

2. ROWS
More information about each parameter is requested from Jeff. This is now applied.

Document version notes

Notes 0.0.4:

1. Eniac Data
Eniac Data AB added to list.

Document version notes

Notes 0.0.5:

1. ROWS
Added LJ System AB and JEFF Electronics in the list.

2. ROWS
Changed ROWS color to Yellow and gave LJ System the orange.

3. ROWS
Approved minor clarifying texts from Eniac.

4. ROWS
Adopted Eniacs suggestion on the extra information for “The list of requested bookings.”

Document version notes

Notes 0.0.6:

1. ROWS
Added Mildmedia in the list.

2. ROWS
Moved Document version notes to the end of the document.

Document version notes

Notes 0.0.8:

1. ROWS
Specified more details about ID variables.

2. ROWS
Changed responseStatus names.

3. ROWS
Changed version value implementation based on discussions.

4. ROWS
Added server.supportedVersion in the response

5. ROWS
Changed status.code implementation and added some standard responses.

Document version notes

Notes 0.0.9:

1. LJ System
Change the term “appId” to “clientID”.

2. LJ System
Added status.code’s based on the HTTP standard codes.

3. LJ System
Changed the term “hash” to “token”.
